Chapter 12: Conclusion

Introduction

Chapter 1

Introduction

It’s a well known fact that a short person has a disadvantage in many fields of endeavor. A person with a height disadvantage can find himself (or herself) falling behind taller people in athletics, in the world of business, where statures gives dominance to conversations, and of course in one’s personal life, where it’s an undeniable fact that taller men and women seem to be more attractive to the opposite sex.

How many times have you heard someone say that because their parents are lacking in height, that they too stand no chance of being very tall? They live their lives complaining about their height (or lack of it) and irritated about how they received the short end of the stick.

With that in mind, it’s obviously everyone’s dream at some point in their lives to be as tall as possible, especially in the growing years; and once growing seems to have reached it’s limit and a person seems to have reached your maximum height, it’s the source of disappointment to many people to find that their maximum height is much less than that of others, and it’s not easy to go through life with this disadvantage in tow.

Modern science can change the equation…

But with revolutionary new methods it's no longer necessary to be satisfied with a stature that's less than desirable. Using little known facts about the human body your height can be enhanced by 2-3 inches with some modest effort, and potentially even more than that for the seriously dedicated individual.

While genetics does hold significant blame for your height, there are actually other things to take into consideration as well. Your height doesn't have to be left in the hands of fate. You too can make a difference to how tall you become. People both young and old can help to increase their height. However, younger people will generally have the edge and achieve faster results.

Minor factors such as how you carry yourself, what type of diet you follow, and what kind of, if any, supplements you take, can all have an impact on just how tall you are or appear. This book will tell you how you can achieve this. We'll review ways to enhance your height to its greatest potential during the growth stages.

You will also learn what can actually disrupt your height growth along with a few effortless ways of increasing your present height. Last but not least you'll be educated on which scams you should be cautious of so you don't waste your money or time on something that won't work.

Yes, these efforts might take some time and patience, but as you very well know, it'll be worth it, and the results are virtually guaranteed. The height increase, of course, varies from individual to individual, but you can not only attain the increase in height that I've specified, but even improve upon it if you continue doing the exercises given in this book for a longer period of time.

Best of all, the increase in height is permanent and will last you for the rest of your life.

Dedication is key to making the program a success.

However, there's one point that I have to insist upon, and that is that you follow this program carefully and in its entirety. Shortcuts, or

skipping out sections of the program, or missing out on certain areas like diet, for example, are not acceptable, because the program only works if it's taken in its entirety and applied consciously for between nine to ten weeks, upon which you'll certainly see an increase in height.

You need to believe in the program and you need to focus on the program, and in doing so will benefit immensely, growing inches in the space of weeks. Remember that it isn't merely absorbing the knowledge in this book that will give you inches of increase in height, but applying that knowledge practically as outlined here.

Applying the knowledge in this book is easy…

On the plus side, it's very easy to apply the principles in this book with a step by step approach to the exercises.

You'll have your exercises and your diet charted out week after week and month after month in a manner that is effortless to follow.

All you need to do is to look up the exercises that you have to do for the day or the exercises that you have to do for the week, and then do them.

For best results, you should do the exercises twice daily: once when you wake up in the morning, and once just before going to bed.

Predict Height:

In the case of children, you can use growth charts to track a child's height development but they are only one of the many ways to make sure a child is healthy, growing, and properly developing.

We'll discuss all the reasons why charts will never be right-on because of the many various points that play a role. The below charts however can be a rough guideline to give you an idea.

More Charts can be found at:

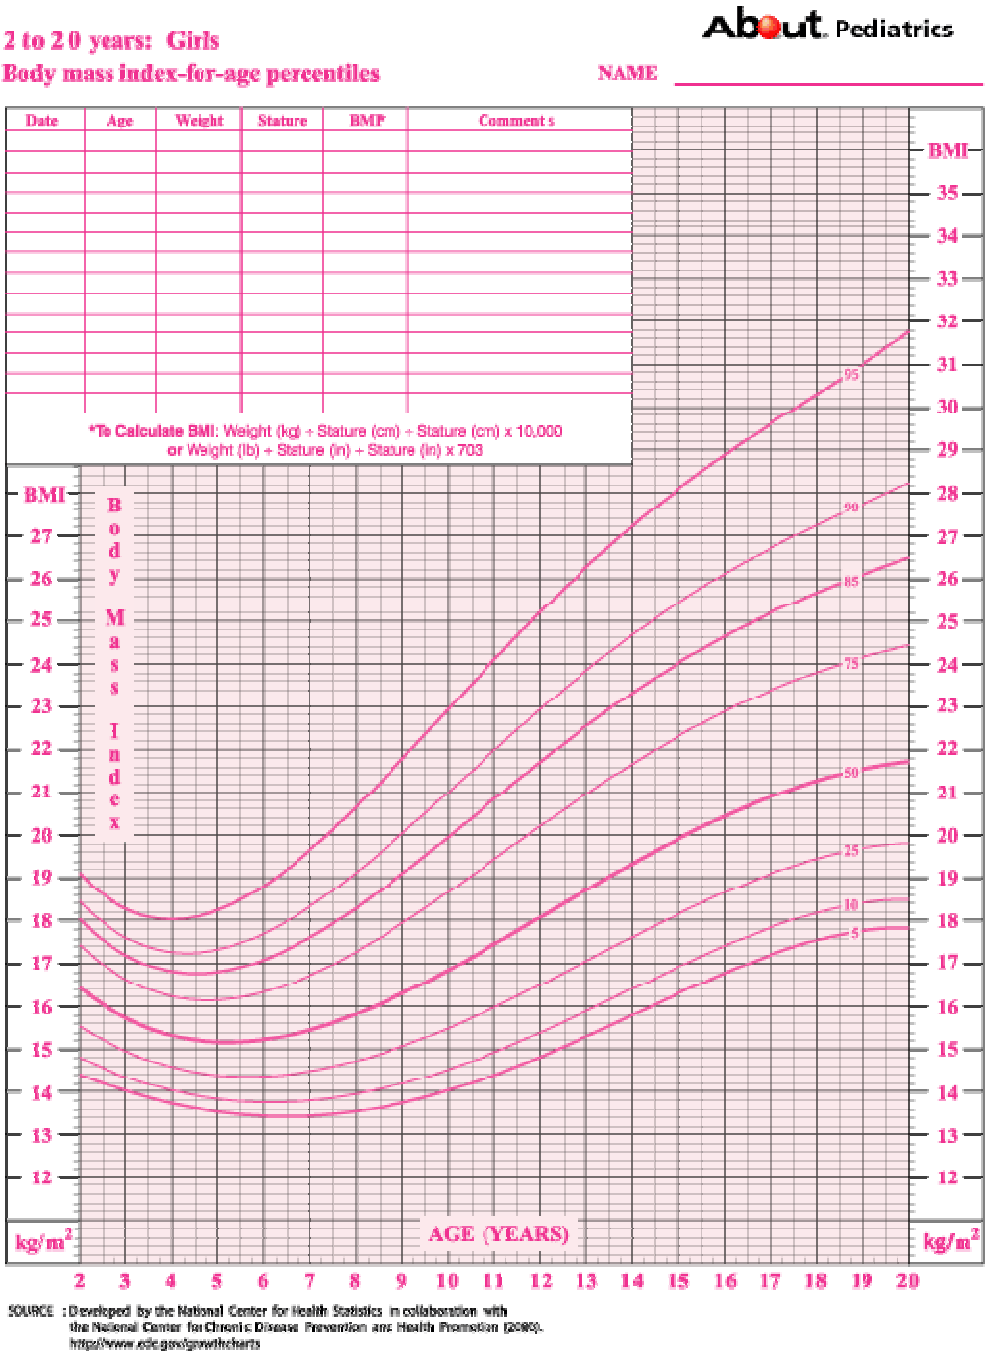
Girls Body Mass Index (BMI)



The principles behind this program:

Before we actually begin on the height-increasing training routine, I'll give you a small run down of the actual principles behind this book.

Now, this book contains a revolutionary new technique that is based upon scientific studies that show that often a person is prevented from reaching their full growth potential by a premature compressing of the disks of their spine. This is usually through "exertion" or through the weight of the body itself as it grows older.

Whatever the reason, it's this pressure upon the spinal disks that stops a person from growing to their complete height potential. To illustrate this, did you know that simply removing pressure from the disks of the spine can immediately give you a height increase of 1-2 inches?

This 'decompressing the spine' is a basic principle of this book, of course, but there's much more – sophisticated exercises and a complete diet plan.

The exercises given here will not only teach you how to decompress the spine to gain inches in height, but also how to take in all the nutritional supplements necessary to allowing the body to make this height permanent.

But how do you know this will work?

Well, you can try an experiment. You can sleep flat on your back without a pillow for between eight to ten hours. This will decompress your spine.

Measure your height just before you go to sleep, and measure your height just after you get up, and you'll find that there can be a difference as much as an 1-3 in your height between these two times.

That's why its very important that you do the exercises explained din this book just before going to sleep and just after waking up.

Everyone is taller in the morning, but by afternoon the extra height is lost as the disks of the spine naturally compress again. Why you never noticed this you might ask? Well, simply because it affects everyone and therefore you won’t notice others shorter or taller because your height has changed too.

The point of the training…

What we're going to do is we are going to take the pressure of the spine by doing different exercises and making certain lifestyle changes, and we're going to give the body the time it needs to grow, to make this increase in height permanent.

During this program, I would advise you to sleep at least eight to ten hours a night, because sleep takes the pressure of your spine and allows for growth at the same time. It's also necessary that you sleep flat on your back without a pillow, as I mentioned earlier, because this allows the spine to be perfectly aligned and allows for real growth in height.

An activity that takes the pressure off the spine is swimming, so if you like swimming, I would encourage you to do a great deal of it, because this will not only keep the muscles in tone and keep your body healthy, but will also actually massively help your efforts to enhance your height.

Another activity that increases your height are pull ups, which naturally stretch the spine. Conversely, you need to avoid any activity that compresses the spine at least for the time of this height-enhancing course. At the end of this course your height increase will be permanent and you can resume these activities.

NO weight-lifting!

One of the main activities I have to warn you against, of course, is weight lifting, because when you lift that much weight you're unnaturally compressing the disks of your spine and you're in effect negating the very efforts you're making to increase your height by doing this course.

Weight lifting is a complete no-no, because it will compress your bones and work against what we're trying to achieve in this course.

Being overweight is out:

If lifting weight negates the program, then being overweight certainly counts as lifting weight. All those extra pounds/kilos compress the spine, you know. If you're overweight, you need to lose the excess weight before you can get the most of this program work.

Maximum effort:

One point I have to urge is effort. You need to put your heart and soul into these exercises, follow the course exactly and correctly, and push yourself as much as you can to get the maximum possible results from this program.

Diet:

One last point that I'd like to mention in the course of introducing you to the program is the question of diet. Now, this program doesn't call for any very specialized diet, but it does call for a highly varied and balanced diet, as well as a special nutritional cocktail that stimulates production of the human growth hormone, without which an increase in height is perhaps impossible.

But the whole topic of nutrition belongs in a chapter of its own, so let's deal with it in the next chapter…

Nutrition

Chapter 2

Homemade HGH Cocktail

Ingredients:

- 1 Tomato (Medium Sized)
- 40 grams of Broad Beans without the Shell (1/3 Cup / 1.5 Ounces)
- 40 grams of White or Red Cabbage (1/3 Cup / 1.5 Ounces)

*Tomatoes contain generous amounts of Gamma-Aminobutryic Acid

*Broad Beans contain generous amounts of L-Dopa

*Cabbage contains generous amounts of L-Glutamine

Note: If you can't find Broad Beans you can replace them with Fresh Green Beans, Fava Beans or better yet with L-Dopa supplements that can be bought from here: www.GrowTaller4Idiots.com/l-dopa.php

Preparation

Mix all raw ingredients in a blender until they turn into liquid. If needed, mix in some water to get the consistency wanted. You can also add sugar or pieces of chocolate to improve the cocktail taste. Now drink and enjoy your HGH level increasing by 300% or more.

Consumption

The above amounts are for a 1-2 time supply; depending on your body weight and appetite. If for example you can take the cocktail all at once, you need to do so. On the other hand, if it's too much for you, it's fine to take it in 2 times.

The HGH cocktail should be taken just 30-60 minutes after each exercise session. If for example you do the exercises in the morning as well as in the afternoon, you must take the cocktail twice.

Broad Beans Photo

The second aspect of nutrition: A Balanced Diet

Now I'm going to talk a LOT about diet, and what you should (and shouldn't eat). But if you'd like to skip all that talk, here's an excellent diet plan to enhance your height. Quantities are not given, but try to take in a little more rather than a little less. ***Above all, DO NOT starve yourself.*** **This is crucial to the success of your height-building program.**

Frequently asked questions about the Diet Plan

Q: What should I eat? How much should I eat? Do you have any other advice?

A: You need to stick to the Diet Plan perfectly, if at all possible. One thing that I might mention is that in following this diet you need to be sure that you're eating enough. Remember that your body will be *growing*. You *must* provide it with the nutrients it need to *sustain* that growth. DO NOT starve yourself – it is far better for the success of this program to take in too much rather than too little. At the same time there's no need to go on an absolute eating binge either. Approach this diet with common sense as your ally.

Q: Do I need to take in anything else besides what you've mentioned in your Diet Plan?

A: Surprisingly, *yes, you do!!* Water. This isn't mentioned in the diet plan, but you need to take in plenty of water, at least eight large glasses a day.

Q: Should I eat seafood?

A: Seafood contains quite a few substances absolutely crucial to enhancing your height, and indeed is part of the Diet Plan.

Q: Can I enhance my height without attention to diet?

A: Impossible! Just as you cannot build a house without bricks and mortar, you cannot enhance your height without the materials with

which to build bones, ligaments and muscles. Following the Diet Plan is crucial.

Q: Is it absolutely necessary to include all the ingredients mentioned in the diet?
A: Absolutely! The Diet Plan has been carefully put together to be both flexible as well as to ensure that you have every single ingredient that your body needs to make your height-building program a success. Even one missing ingredient could turn that success into failure.

Q: Can I skip out on the Growth Hormone Drink?
A: The Growth Hormone Drink contains substances crucial to the success of this program and cannot be skipped *at all*.

Q: What about Vitamin and Mineral supplements?
A: Supplements are just that – supplements. By all means take in supplements. But they must only *add* to the resources provided by a balanced diet – you must *never* attempt to replace a balanced diet with supplements.

Q: Where can I find more information about Diet?
A: Why, right here! The next pages are absolutely full of information about all you need to know about a balanced diet.

A detailed discussion of Diet

And now to a more detailed discussion of a properly balanced diet. It's important to avoid poor eating habits, because if you don't provide your body with sufficient nutrition to fuel growth, then all the exercises that you do in this program become useless.

Think of it as of a structure being built. You can't build a structure without bricks and mortar, so similarly, nothing in your body can be built and no growth is possible unless the raw materials are available to the body to fuel this growth.

Now, generally speaking, a healthy balanced diet should cover most of the nutritional needs of your body.

A healthy balanced diet involves taking in a great deal of protein, carbohydrates and essential fatty acids. There should also be a considerable amount of the essential vitamins and minerals, and, strangely enough, you also need to take in large quantities of water.

Does that surprise you? Well, it shouldn't, because your body is made up of water to a large extent, amounting to about eighty percent of it's mass. So, water is an essential constituent for growth.

Now, there are a few vitamins which are absolutely essential to growth, and you need to eat foods which contain these vitamins, or else take in a vitamin supplement that will supply the same.

Go on to the next page for a rundown on essential foods…

Foods essential to the Body

Generally speaking, **liver** should be an important constituent of any diet, because it contains several growth promoting vitamins, including the **vitamin A**, the **vitamin B6** and the **vitamin B12**.

Another source of important vitamins is **fish liver oil**, as well as **milk** and **eggs**. **Milk** and **eggs** contain a lot of essential substances required by the body - and of course, this includes **milk products** as well.

Generally speaking, you should take in a **variety of meats**, including **beef**, **pork**, **chicken**, **liver** and **kidney** in equal proportions and in a reasonable quantity every week.

Different meats contain different substances, including vitamins, required by the body, and rotating these meats will ensure that your body always has substances it needs to build and grow upon. Pork, as an example, contains the vitamin B1, while the vitamin D is found in fish and fish liver oils, and so is the vitamin K.

Add to this diet a good mix of **vegetables**, and of course **cereals**, and you'll only enhance your ability to make the most of the growth exercises included in this book.

One important vitamin that has not been found in the foods I've been mentioning is the vitamin C. Now, the **vitamin C** is contained in **citrus foods** and is indispensable in aiding the growth of strong bones. It also helps in the building and health of protein cells within the body. Tomatoes and berries, cauliflower and cabbage, and potatoes – all are excellent sources of the vitamin C.

Then there's the **vitamin D**, which is of course available in milk products, which I've already mentioned, but which can be produced by the body simply by taking a walk in the sun.

Another vitamin that I have to mention is the **vitamin F**, which is contained in **vegetable oils** and **various kinds of nuts**, and of course in **sunflower seeds** and **sunflower oils**. Make sure you take in a certain amount of these foods as well to ensure that you don't lose out on the benefits of this essential growth vitamin.

The use of Vitamin Supplements

Generally speaking, I don’t advise a person to rely solely upon supplements for their vitamin needs.

Rather I would say that you need to include all the foods I’ve mentioned in a balanced diet, as well as a good amount of leafy vegetables and, to be honest, as diverse a range of meats, fruits and vegetables as possible.

When you have a vast and diverse range of foods available and you cycle through them, you’ll find that your body can absorb from them virtually any substance that it needs for growth and for good health, and this includes many substances that are perhaps not even known to science today.

Now, besides all these, if you take a vitamin supplement as well, then you’re only going to benefit your body even further.

In other words, a supplement does exactly what its name implies – it supplements your diet and boosts the intake of essential substances to your body, but it cannot replace a balanced diet.

Minerals in your Diet

Now we come to minerals, and the most important of these, of course (it goes without saying), is **calcium**, because without calcium with which to fuel the growth of your bones, making the height you gain with this exercises permanent is all but impossible.

Everyone knows that the best sources of calcium are meat and milk products, but you can also find it in sardines and soybean, as well as in dry beans and dry vegetables. Nevertheless, milk and milk products remain the best sources of calcium.

Another essential mineral is **chromium**, and it's found in different meats, and therefore has already been covered by our discussion. **Chlorine** is also important to the body, but as it's contained in table salt, small amounts of table salt, as much as you have with your meals, is usually sufficient for your chlorine intake.

Fluoride is another mineral that strengthens the bones, and it's usually found in seafood, so if you take in a reasonable amount of

fish, you shouldn't have any problems. Then there's **iodine**, which again is found in both salt and seafood.

Iron is another very important mineral, and indeed extremely essential for both growth as well as for healthy blood and an efficient circulatory system. Generally iron is found in various meats, so the healthy balanced diet that I mentioned earlier certainly covers this as well.

Now, one mineral that you have to be sure to cover is **magnesium**, which isn't easily found in many diets. It's contained in figs, grapefruits, apples, lemons, as well as in various seeds and nuts.

You need to eat a certain amount of these regularly to ensure that your magnesium intake is covered. Magnesium actually helps the body to process calcium and vitamin C, and so is absolutely essential.

Other minerals that are required by the body are **phosphorus**, **potassium**, **sodium**, **sulfur**, **zinc** and a few other substances. All of these are covered by a reasonable balanced diet.

Covering all your nutritional needs…

Let’s recoup. What does a balanced diet consist of?

A balanced diet consists of as wide a range of meats as possible, including liver and kidney, beef, pork, fish and other meets.

You also need to have plenty of milk and milk products, as well as a wide range of vegetables, including basic vegetables such as potatoes and green leafy vegetables.

Add lots of different fruit, but especially citrus fruits, and some nuts and essential oils to the diet, and you have a well rounded, balanced diet that can cover all the nutritional and growth needs of your body.

Another absolutely essential constituent for growth is protein, and this is available in every kind of meat and seafood, as well as in fish and eggs, so make sure you are taking in enough of these, because without protein no growth is possible.

Lastly, the body needs water, and this involves taking in six to eight glasses daily. And that's the basics of what you need to know about nutrition.

Posture and Sleep

Chapter 3

Posture and Sleep

Before we go to the actual exercises, there are two things that we need to discuss, and that's how to develop the correct posture, and developing the right sleeping habits. Posture can be a great deal more important than you think when it comes to gaining height.

Common issues with posture:

It's a total misconception that if you just stand straight or erect, you then have a correct posture.

This isn't actually true, because the way you hold your head, the way you hold your shoulders, even the way you hold your pelvis, all of these are important, and more.

Making small corrections in your posture can considerably enhance your height by an inch or two, which, when taken with the exercises, will continue to encourage growth.

But more importantly, correct posture will not work against exercises, which a wrong posture certainly does.

A tilted pelvis is often an issue, with many people leaning the pelvis forward or leaning the pelvis backwards, resulting in a bent or curved spine when they walk. Look at the image to the right, which shows what a tilted pelvis looks like…

These conditions are generally caused by weak muscles in the stomach and back, and there are exercises in the course of the program that will correct these conditions.

Rounded shoulders are another problem, where a person tends to carry the head and shoulders too far forward.

There's also curvature of the spine, as shown on the image to the left, which is another serious posture issue.

The good news, however, is that all of these issues with posture are easily corrected. Read on, to know exactly how...

Correcting one's Posture…

If you look at the girl in the image on the left, you might think that she had a perfect posture. But if you look carefully, you'll see that she carries her shoulders a little too far forward, leading to a condition called 'rounded shoulders'.

This just goes to illustrate how careful you need to be about posture.

Correct posture:

Throw the head back, and let the shoulders settle into the correct position in a relaxed and comfortable manner.

Hold the chin up, but not in a manner that feels uncomfortable. Keep the legs and pelvis in line with the shoulders, and the spine erect.

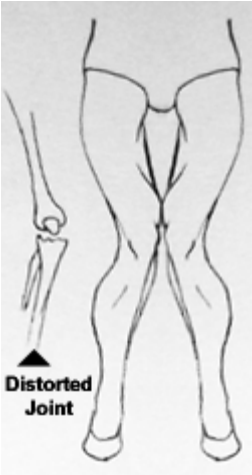
Practice walking around your room with a book balanced on your head – this is excellent exercise for the posture.

Correcting bow legs and knocked knees

Another issue that many people have are problems with the legs, generally known as bow legs or knock knees. In knock knees the knee joints are pushed inwards, whereas in bow legs they're pushed outwards.

Now, these problems are usually caused in early childhood, when parents try to force children to walk upright before they're ready and the joints are properly formed.

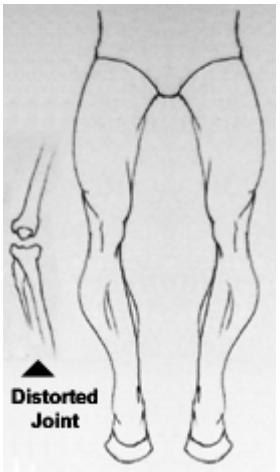
This generally tends to make the legs becoming curved, not along the plane of the joints, but at an angle to the plane of the joint, meaning that the leg is actually curved outwards or inwards.



If you suffer from knock knees, in which the legs are curved inwards, you can walk with the arches of your feet raised, and also place the weight on the outside of your instep.

You'll find that this can be a considerable benefit and that it will tend to correct the problem over time.

In bow legs, in which legs are bent outwards, the remedy is exactly the opposite of the remedy for knock knees, and that is that you should walk with the weight on the inside of the foot.



While these problems will not be perfectly corrected, even with these remedies, nevertheless a considerable improvement may be expected.

Consult a doctor. Many doctors can give you a prescription or recommend special pads that will allow you to automatically correct both these conditions over time.

These pads are usually inserted into your shoes, or sometimes you can buy special shoes for this purpose, and merely correcting this

can add an inch or two to your height, depending upon the severity of the condition.

And of course I might mention that it gives you a very dignified appearance when you’re able to walk erect and walk correctly with the right posture.

Correct Sleeping Habits

Another important aspect that we need to discuss before we actually begin on the exercises themselves is the manner of sleep.

Now, sleep is crucial to our program, because our program concentrates upon maximizing height by decompressing the spine as much as possible.

The spine decompresses most of all during sleep, and this is exactly where many adults fail, because in the stressful world of today we find many adults sleep perhaps just four hours a night, which is hardly sufficient.

Remember that lying in bed takes the pressure off the disks of the spine and causes your height to increase.

You may not realize it, but you're actually a good deal taller when you wake up in the morning than you were when you went to sleep at night.

Another important aspect of sleep is that it promotes growth. This means that not only will you grow taller in sleep, but that the body will build the bone and muscle necessary while you're sleeping to make that growth permanent.

Of course, this is only small part of the program, with the exercises being a real focus of the program and real means by which growth is achieved and sustained. But it's nevertheless crucial to the success of the program that you get enough sleep.

So, how much sleep is considered enough? Ideally speaking, you need eight to ten hours of sleep.

If you think this is a lot, it isn't actually, because the more sleep that you get, the more successful will be this program.

Read on, to learn how to develop the right sleeping habits…

The correct position to sleep in

Now we'll talk about the position you sleep in. As we allow the spine to decompress in sleep, obviously we should place our body in a position most suited to this decompression.

First of all, you need to get rid of the habit of using a pillow. The habit of using a pillow is one that is inculcated in us in early childhood. It's actually an erroneous assumption that a pillow makes your sleep more comfortable, because it does not, it's merely force of habit that makes a pillow seem more comfortable.

When you get rid of the pillow, you place the spine in a naturally straight position that allows for maximum decompression of the spinal disks.

Bad posture in sleep

So, one thing that's important is learning to sleep flat on your back.

The most natural position for the spine is with you lying flat on your back with your arms comfortably extended towards the foot of your bed, as well as your legs also.

Sleeping in a position that curves the spine in any way will cause problems with decompressing the disks, and could affect the success of the program.

Now, since you're not used to sleeping in this way it might feel a little odd at first, or a little uncomfortable when you sleep in this position, but you'll find that the human body is very adaptable, and after a few nights you'll find this position feels perfectly natural and indeed over time you'll find it far more comfortable than the sleeping habits you now observe.

The Global Approach

I have to stress here that this program for increasing height uses a global approach, in which we address not merely the basic aspects of height increase, but rather the global aspects of height increase, in the sense that this program, to succeed, needs you to observe correct habits of posture, of diet, of sleep and many other things.

When we mention something in the course of this book, or the course of this program, it's because it is essential, *absolutely essential* to the program.

So give every aspect that I mention the importance it deserves, and together we can make this program a success and add several inches to your height as well.

The next chapter will map out your exercise plan for the entire course of this program – study this plan carefully before going on to the exercises themselves…

Location of the Exercises in this Book	The exercises are described in detail in Chapter 5	The *Introductory Exercises* are in Chapter 5. The *Focused Stretching Routine* is described in detail in Chapter 6	The Advanced Training Program is described in detail in Chapter 7	If you wish to continue to enhance your height to the maximum possible, continue the Advanced Training Program in Chapter 7 *indefinitely*
Important Details	There are five exercises, and they must be done two times a day, once in the morning, just after awakening, and once just before going to bed.	The Focused Stretching Routine consists of three sets of five exercises, that must be done *in rotation* for a period of three weeks. This is done *along with* the Introductory Exercises that you did during the first week.	The Advanced Training Program consists of ten exercises to be done two times a day, once in the morning, just after awakening, and once just before going to bed.	Continue to do the Advanced Training Program two times a day, once in the morning, just after awakening, and once just before going to bed.

Week One: The Introductory Exercises

Chapter 5

Week One: The Introductory Exercises

Now we'll begin the exercise routines, and you'll be carefully guided over the next few weeks as to what exercises to do every day. All you need to do is to look up the exercises that you're supposed to do and to do them conscientiously, and you'll see an increase in height. Bear in mind that an increase in height might take between four to six weeks to actually show.

Nevertheless, if you follow this exercise program correctly and conscientiously, the increase in height is not only guaranteed, but will also be permanent. The exercises are simple enough and will not be difficult to follow.

And now let's go on to the first week of training.

The first weeks of training constitutes what we will call the introductory exercises. Now, the introductory exercises are important to remember and do correctly, because you'll be doing these exercises virtually all through your training. Yes, you'll learn more

advances exercises later, but any more advanced exercises that you learn will be done in conjunction with the introductory exercises.

So when and how do you do the introductory exercises? Well, the introductory exercises have to be done twice in a day: once when you first wake up in the morning and another time just before you go to bed. Now, there's a particular reason for this, and that reason is that the spine stretches during sleep, so doing the introductory exercises just before you go to sleep will ensure that the spine is stretched to its maximum, and doing it just after you wake up will ensure that this natural stretching of the spine is augmented by the exercises themselves.

How long do you have to do these exercises? Well, in daily terms, it should not take you more than fifteen minutes or so to do the exercises. The introductory exercises should be done in the course of a week or so. I'll be giving you step by step instructions as to how you'll go about them. After the first week I will teach you more advanced exercises that you'll add to the course of introductory exercises that you do.

Once more, let me repeat that the introductory exercises will be continued all through the course. Before we start the exercises, let me give you a little bit of advice, and that is while it's necessary to be very dedicated and to push your body as much as reasonable, you must not allow your body to be stressed or strained.

This means doing the exercises in a reasonable and intelligent manner and not pushing your body so hard that it results in great fatigue of muscles, ligaments and joints, and perhaps an injury. You must above all not injure yourself, because an injury would cause an interruption in the program, that would perhaps necessitate starting the program all over again once the injury healed.

So, what you need to do is, you need to push yourself, but do it in an intelligent manner. Go as far as you can without going too far and injuring yourself. Be careful, be dedicated, and let's begin the program.

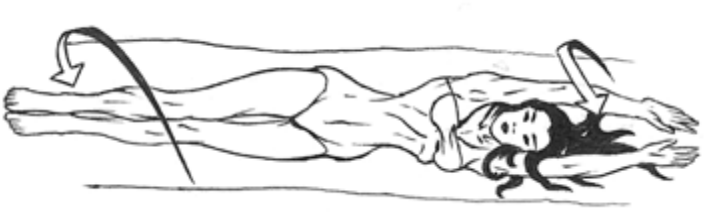
The Introductory Exercises:

The 1st Exercise

When you wake up in the morning, your spinal disks are already fairly well decompressed. But you can improve upon this by doing a little stretching.

Lie flat on your back with the legs extended and the arms reaching up over your head. Now stretch. Firstly stretch your legs down as much as possible, and the arms upwards as much as possible, so that the whole body is stretched to the maximum.

Now gently begin to twist and turn the body.

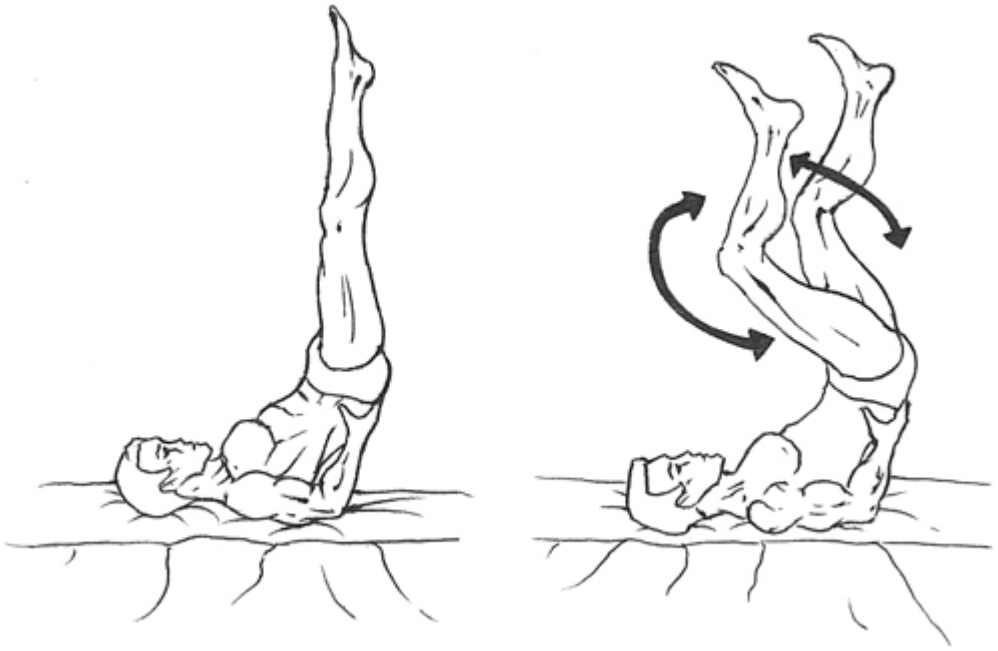


Generally speaking, your aim is to stretch every joint of your body in every possible direction. Be careful not to injure yourself though. Keep the movements gentle and natural.

The 2nd Exercise

This exercise is relatively simple. Lie flat on your back. Now, extend the legs upwards and prop your hips up with your upper arms so that your spine is actually off the bed.

The weight of your legs should be taken by your arms and elbows, and of course by the upper back. The feet should be extended directly upwards, and the legs at a right angle to the floor.



Now, begin to work the legs as if you were working the pedals of a bicycle in a rotary manner. You need to continue this movement for around a minute or so.

The 3rd Exercise

Sit up with your back erect. Support this position by placing your arms at your side, resting them on the bed.

Now, rotate the head, first clockwise and then anti-clockwise, and do this several times over.

Extend the head forward as much as possible, and then backwards as much as possible, extend it to the left, and then to the right as much as possible.

This loosens the vertebrae and the joints of the neck. Be careful that while you extend your head in each direction as much as possible, you nevertheless don't strain or injure your neck in any way.

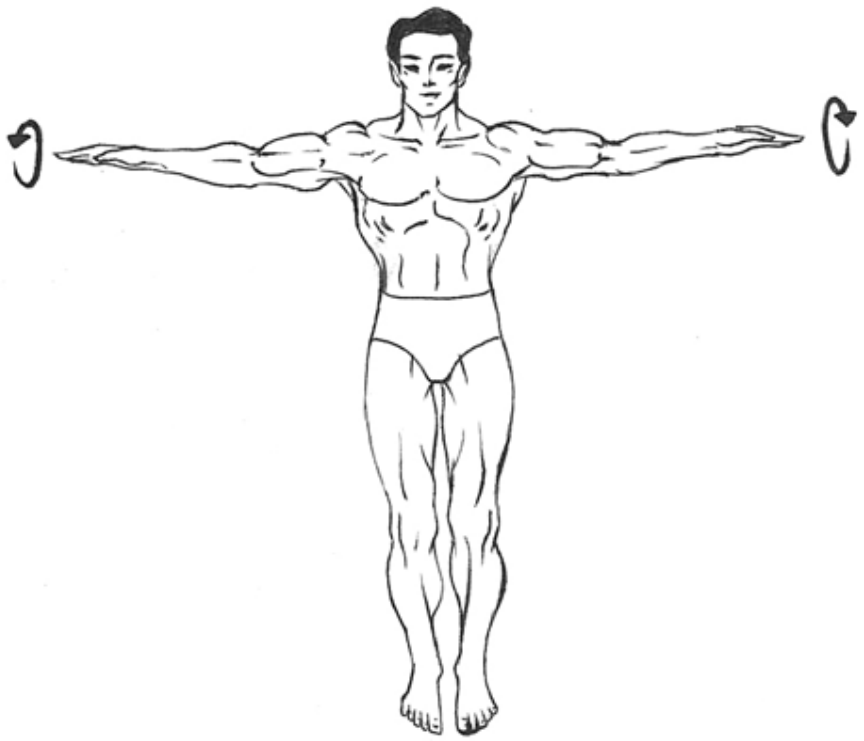
The idea is to push your body as much as possible without pushing it too hard and causing an injury.

The 4th Exercise

This exercise is relatively simple – just stand with the arms extended and reach out as much as possible to each side.

Then begin to rotate the arms in circles – each circle being just about two feet across.

Try to move the hands back as much as at all comfortable.

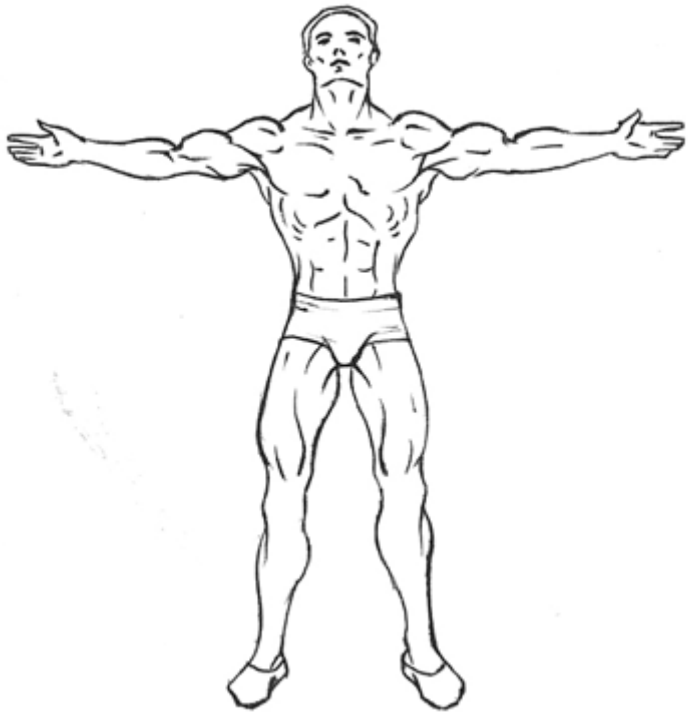


After rotating the arms ten times, start to rotate them ten additional times in the opposite direction.

The 5th Exercise

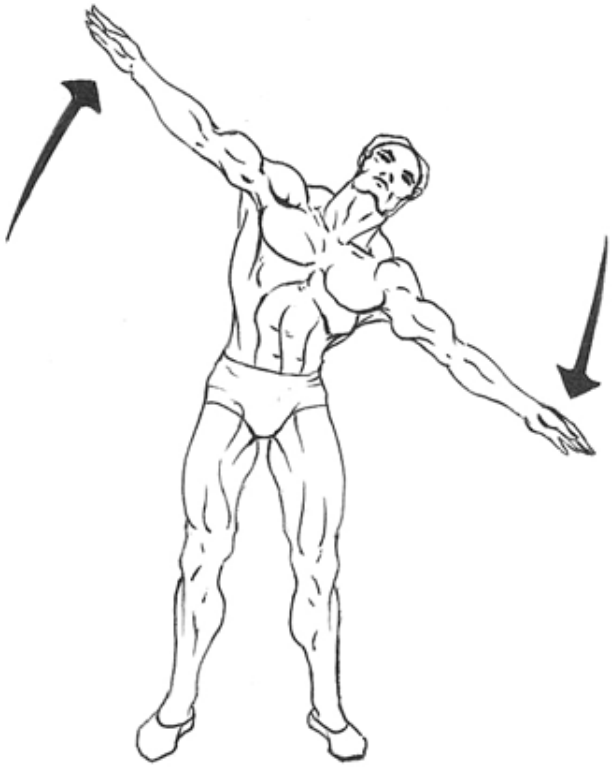
We'll be doing this exercise in two parts.

First, stand erect and extend your arms straight out, as shown in the picture below, horizontal to the floor.



Stretch the hands outwards as much as possible to extend the bones and the joints of the arms themselves, as well as those of the shoulders. Try to reach outwards in each direction as much as possible. Remember to keep the stretching comfortable – don't strain anything.

The second part of this exercise is to tilt the body at the waist downwards to the left as far as it will go, and then to the right. Keep doing this for around a minute or so.



After this you can place your hands behind your neck and continue this movement for another minute.

This exercise relaxes and loosens the vertebrae of the spine even further, and it also massages the vertebrae and increases the flexibility of the spine thereby preventing injury in the exercises to come.

The 6th Exercise

Stand with your face and body touching a wall. Try to touch the body to the wall as much as possible.

Now reach with your hands as high as you possibly can. Stretch higher. You must attempt to reach as high up the wall as possible.

Remember to keep the heels on the floor and not to raise them under any circumstances.

When you reach the maximum height that you can, you need to stay in that position for up to five to ten seconds.

Then you can lower your body to its original position.

Do this ten times.

This is only the first part of the exercise – go on to the next page for the next part…

Now turn and place the right side of your body against the wall and with your right hand reach up the wall in exactly the same manner, and do this three times.

Then do the same with the left side of your body.

Then stand with your back to the wall and reach up both hands as high as you possibly can, and do the same stretching motion three times.

This completes the set of introductory exercises that you're supposed to do for the first week.

These exercises are crucially important in that they stretch and limber both the spine and the joints and prepare the body for the exercises to come.

They also correct any defect in posture that a person may develop over the years.

You must do these exercises twice a day, once in the morning and once in the evening every day for the entire week before going on to the next set of the exercises, that I call the Focused Stretching Routine.

Weeks Two to Four:

The Focused Stretching Routine

Chapter 6

Weeks Two to Four: The Focused Stretching Routine

Remember that the Focused Stretching Routine has to be done in conjunction with the introductory exercises.

This is to say that every morning and every night you'll first do the introductory exercises, and then do the exercises of the Focused Stretching Routine.

The Focused Stretching Routine consists of fifteen exercises or so. I will teach you a three day routine in which to do these exercises in.

On the first day we will do five exercises, on the second day we will do five different exercises, and on the third day we will do five exercises that are different from these.

In other words, you'll do fifteen different exercises over a three day period.

This three day period will be repeated again and again for a total period of three weeks.

I hope that's clear: you'll repeat the three day cycle that I teach you for a period lasting three weeks.

Remember to pay attention to the nutrition plan and to keep your diet full and balanced for maximum results. Remember that growth doesn't occur without attention to nutrition.

To be more specific: Growth does not materialize itself from "thin air"; it comes from the food that we eat.

The Focused Stretching Routine – Day One

The 1st Exercise

This exercise is very simple. Hold a chair in front of you.

Stand behind the back of the chair and around a foot away from it.

Hold the chair with your arms.

Now, moving slowly and standing on one leg, swing the other leg backwards and up as high as it will go.

Slowly swing the leg down and do exactly the same thing with the other leg. Do this exercise roughly ten times with each leg.

The 2nd Exercise

Lie flat on the ground and bring one knee up so that it's folded in front of your chest.

Now, grip your knee with your hands and pull it towards you, so that it actually touches your neck, as shown in the image below...

Hold it in this position for around five seconds, then release it and allow it to extend to its natural position.

Do the same thing with the other leg.

Do this exercise roughly ten times each leg.

The 3rd Exercise

This exercise actually derives from an ancient Chinese exercise. Stand comfortably erect, in a normal and correct posture.

Now raise your hands above your head and extend them upwards. As shown in the picture to the right…

Now go onto your toes while continuing to reach upwards.

This has the effect of stretching your entire body.

As you stretch your body upwards, you should hold this position for about a minute at first, and try to extend it to two minutes the second time you do the exercise. And for every time you do the exercise after that, you should do this for three minutes at a time.

The 4th Exercise

This exercise is generally done in two parts.

The first stage of the exercise involves lying flat on the floor, face down, with your arms behind your back.

Now, raise the upper portion of your body and your legs at the same time. Remember that you must not bend your knees.

When your upper body and your legs are off the floor, rock your body in this position forwards and backwards a few times.

You need to do this exercise at least five times. Then go on to the next page for the second part of this exercise…

After you finish the first part of this exercise, extend your arms in front of you while still in a face down position.

Now raise one of your legs upwards and hold it in this position for around twenty seconds or so.

Put the leg down and raise the other leg upwards, and hold it in the same position for the same amount of time.

Do the exercise five times with each leg.

The 5th Exercise

Stand with your arms stretched above your head and stretch the body upwards slightly.

Now, tilt the body to the side as much as possible, first to the left, and then to the right.

Count this moment as one and do ten of these movements.

Rest for a little while and repeat this exercise again.

The Focused Stretching Routine – Day Two

The 1st Exercise

Lie flat on your back, with your knees bent and your palms flat on the floor, your arms lying comfortably beside you.

Now arch the body upwards, taking the weight of the body on your shoulders and on your toes alone, as shown below...

This exercise articulates the vertebrae in a very beneficial fashion, and promotes considerable growth.

You should do this exercise at least ten times, and each time you do it, you should try to increase the arch that your body forms.

Try to improve on the exercise every time you do it as the weeks go by.

Remember though that all these exercises manipulate the spine, so do try to avoid injury and by all means try to stretch the spine, but to a reasonable and sensible extent.

The 2nd Exercise

Sit on a chair. Now, extend your body stiffly, so that it's extended completely straight, but in a diagonal manner, as shown in the image.

The only point of contact with the chair should be your upper shoulders and your upper thighs.

And your body should be as erect and straight as possible.

Now, fold your body up, bring your chest forward and your knees up, so that your knees touch the chest.

Use your arms to press your knees to the chest.

Repeat this process at least five times for maximum effect.

The 3rd Exercise

This exercise is very simple, but for many people is also very difficult to do correctly.

Stand with your feet slightly more than a foot apart. Now, with your hands on your legs, bend forward without bending the knees.

Bend your body forward, sliding the hands down your legs until your hands are about level with your shins.

Remember that the knees must not bend.

You'll find that there is a considerable strain in the hamstrings at the back of the legs, and in the spine as well.

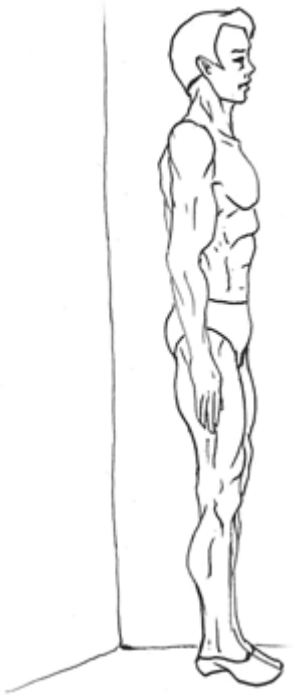
This is perhaps one of the best tests of flexibility of the spine.

Ultimately, you should be able to touch your hands to the floor. When your hands touch the floor, your palms should be completely in contact with the floor. In other words, your hand should be flat on the floor.

This isn’t something you can achieve in a single day, and I would suggest that you aim to achieve it over the course of a three week period.

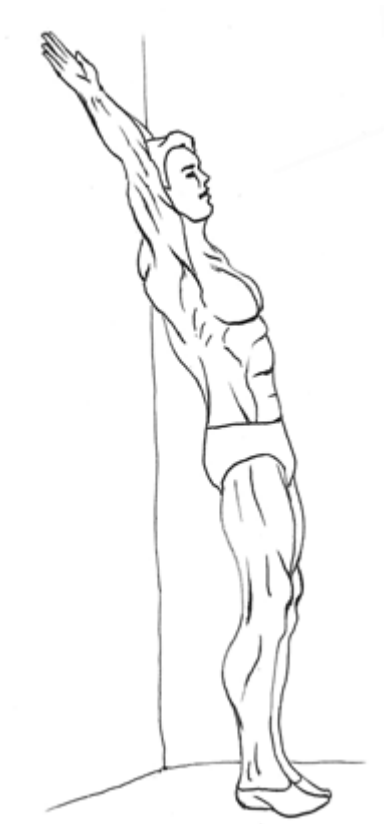
The 4th Exercise

Stand with your back to a wall. You should be around two feet away from the wall.



Slowly, without bending your knees stretch your body backwards until your fingertips touch the wall.

This might be very easy at first, but you'll increase your distance from the wall by between three to six inches on every additional day that you do this exercise.



Ultimately, you should be about four feet from the wall and still be able to stretch your body backwards so that your fingertips touch the wall.

This is an incredibly good exercise for building flexibility of the spine, especially the ability to manipulate the spine backwards. You should do this exercise at least seven times, every time you execute it.

The 5th Exercise

This exercise is called the bent-forward lunge.

You start this exercise in a comfortable standing position, as shown in the picture to the right…

From a standing position, move one of your legs forward until it is far ahead of the other leg. The knee bends at the same time. The leg that is behind the body should be extended without bending the knee.

Now, without lifting the rear leg off the floor, stretch your body in the forward direction as much as possible and hold that position for at least three seconds.

Do this five times before changing the positions of the feet and repeating the exercise with the other side of your body.

The Focused Stretching Routine – Day Three

The 1st Exercise

For this exercise, stand with your feet about shoulder width apart.

Now, sit down as if you were sitting in an imaginary chair.

Your hips should not go lower than the level of your knees.

Extend the hands in front of your body, and when the knees bend, they should bend straight forward and not sideways.

Do this exercise around ten times or so.

The 2nd Exercise

Sit with your legs extended straight ahead of you and with the feet locked under some piece of furniture.

Now, revolve the torso, first in a clockwise manner, and then in an anti-clockwise manner.

Do the exercise around ten times in one direction, then rest for a few seconds and do them ten times in the other direction.

Repeat the procedure at least four times.

The 3rd Exercise

Stand with your feet around shoulder width apart and with your hands behind your head.

Now, bend forward while extending your hands and touch your fingers to the floor.

To make the exercise more difficult, try to do it with your feet together.

When you can touch your fingers to the floor easily, attempt then to touch your palms to the floor.

The 4th Exercise

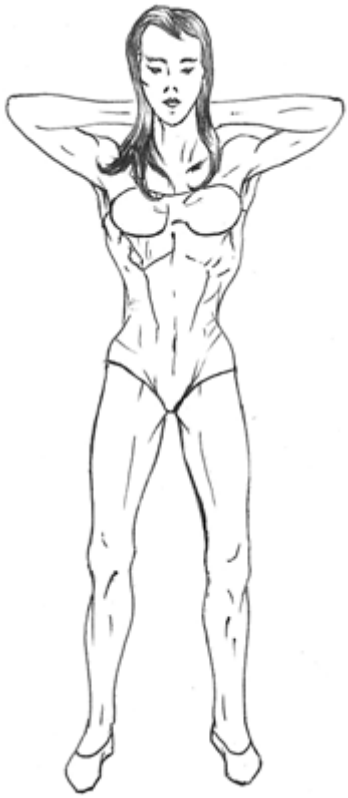
Lie flat on your back with your arms extended above your head.

Now, arch your back so that your weight is taken solely by the backs of your heels and by your shoulders.

Arch the body upwards as much as comfortably possible and try to increase this arch every time you do this exercise.

Do this movement five times.

The 5th Exercise



This exercise is similar to some other exercises that you've done before. Stand with your hands behind your head and your feet about shoulder width apart.

Now bend forward trying to touch your head to your knees.

Don't overdo things over here, and most of all don't try to bend forward by placing pressure on your neck with your hands.

The amount of your bending forward should depend upon the flexibility of your spine, and since you're stretching the ligaments and vertebrae of your spine, do this carefully, without extending yourself too far.

Aim for a gradual increase of the flexibility of your spine over a period of three weeks rather then trying to stretch your spine in a single day, which can be dangerous and potentially disastrous. This concludes the exercises of the Focused Stretching Routine.

REPEATING THIS THREE-DAY ROUTINE…

Remember that you'll have to repeat this three day routine again and again for a period lasting three weeks or so. At the end of those three weeks your spine should be a great deal more flexible than it was before, and you should be able to extend your height by at least two inches.

Remember that you have to do the introductory exercises along with the stretching routine. This may extend the amount of time you spend on your exercises in the morning and in the evening to about half an hour, but the results are worth it.

You must stay focused and not miss out on any part of the routine, as well as pay attention to diet, without which the growth of muscles, ligaments and bones cannot be sustained. Your diet and human growth hormone levels must be enough to sustain the levels of growth that your body will be experiencing at this stage.

Your diet is crucial, because without the diet it's impossible to make the increase in height that you experience permanent, and this makes the exercises rather useless.

If you do these exercises as I've described them, doing the introductory exercises for one week and then proceeding to do the introductory exercises along with the Focused Stretching Routine for another three weeks, you should experience an increase in height that can range up to two or three inches or so.

But without a diet that will provide materials to the body to make this increase in height permanent, you'll find that you'll lose this height in the time to come, especially if you stop doing the exercises.

Remember that this program is a composite program that involves a mix of scientific principles, specific stretching exercises and diet, and you must follow this program in its entirety for the best results.

Week Five to Nine:

The Advanced Training Program

Chapter 7

Week Five to Nine: The Advanced Training Program

Now that your body is sufficiently toned and your spinal flexibility is sufficiently enhanced, you can go on to the advanced stage of our training program.

Though it’s possible that some people already experience an increase in height after following the initial stages of the program, that is four weeks, generally speaking, it’s only after the second week of the advanced training program that an actual visible increase in height is observed.

So what’s the advanced training program like?

Well, there are ten exercises, and these have to performed every single day, morning and evening, for a five day cycle - after this you can take a rest for two days.

In fact the rest is essential that the body may recoup and grow, and then you trigger another seven day cycle.

The Advanced Exercises:

The 1st Exercise

For the first exercise you'll stand erect and place your hands behind your head. You'll push forward with your hands and use the muscles of the neck to resist this pressure.

While maintaining this tension, slowly allow the head to move forward as much as possible.

Usually you should end with your chin resting upon your chest. Now slowly, and I mean slowly, relax the tension and then allow your head to return to its normal position.

Once this is done, you'll need to repeat this exercise ten times, after which you can take a short rest and do it ten times more.

The 2nd Exercise

Stand erect and lock your thumbs together behind your back.

Now, move your shoulders as far forward as you can with your thumbs still locked.

Then move the shoulders back as much as possible, then raise the shoulders as much as possible, then lower them as much as possible.

Now start moving the shoulders in a circular motion, first clockwise, and then anti-clockwise.

Please do this exercise with some care and don't injure yourself, because it can be quite a strain on the shoulder joints. Consider each set that I described as one, and do about six of these sets. Move the

shoulders up, then down, then forward, then backward, then rotate them clockwise, then rotate them anti-clockwise. In each section of the exercise push the shoulders to the limits of their flexibility.

The 3rd Exercise

Stand with one foot ahead of the other and your entire weight on the forward foot.

The forward foot should be completely straight without the knee bent.

Extend the hand on that side of the body so that it faces straight out ahead of you.

Now, bend the knee of the forward foot and bend your body forward until your hand touches the floor, as shown in the image to the right.

Then go a step further and try to touch your head to the floor, which incidentally will be impossible, but making the attempt will provide advanced stretching to the disks of the spine.

At this point the trailing leg is extended straight out, and note that it is not lifted from the floor.

Do this exercise ten times, then put the other foot forward and do the same exercise mirroring it with the opposite side of the body.

The 4th Exercise

This is an advanced version of an exercise that you did earlier in the program, and is based upon an ancient Chinese exercise.

Stand comfortably with the feet together and extend the hands over the head.

Now, stretch upwards while going up onto your toes. Stretch both arms as high as you possibly can, and while in this position, throw your head back and look upwards.

Your head should go backwards as much as you can possibly send it. Stand in this position for a few seconds and return to normal.

You need to do this exercise ten times.

The 5th Exercise

Stand comfortably with the feet about your shoulders' width apart and with your hands resting on your hips.

Now, bend forward and attempt to touch the toes of the left foot with your right hand.

Even if you cannot touch your toes, continue to attempt to do so and you'll find that after a few weeks you'll manage to do it.

Now straighten up, and then bend forward again and with the left hand try to touch the toes of the right foot.

Count both these motions as one and do the exercise around ten times or so.

The 6th Exercise

To do this exercise you simply sit on the floor with your back erect and your legs extended in front of you.

You start your exercise with your hands placed comfortably on your hips. Now, you extend your hands forward and attempt to touch your toes.

Of course, if you can touch your toes, that's very good, but if you can't, you keep pushing yourself until at the end of a week or two you'll find that you can indeed touch your toes.

After this, return your hands to your hips. Repeat this procedure at least five times. When you've done this, move the legs apart slightly,

and try to touch the toes of the opposite foot with your right hand. After that, try to touch the toes of your right foot with your left hand.

Count this motion as one and do five.

The 7th Exercise

Sit on the floor with your knees bent at about a 45 degree angle.

Your back should be erect, and your hands should be behind your neck.

Now, twist the torso so that your elbow touches the opposite knee.

Then twist the torso in the opposite direction, so that the other elbow touches the other knee.

Count both these motions as one and do five.

If you find that the exercise is too easy, straighten your legs a little bit and you'll find that it becomes more challenging.

The 8th Exercise

Lie flat on your back and raise the legs so they're extended straight up vertically.

Now spread them apart without bending the knees as far as is at all possible.

After this bring them together and cross them over as far as is at all possible.

Count this as a single movement and do this movement ten times.

After a little rest you can do this exercise another ten times or so.

The 9th Exercise

Lie flat on your back comfortably.

Now, with the body's weight resting on the shoulders and on the arms, which are at your sides, raise the legs so that they're straight up in the vertical position, and then slowly lower them down on the other side, so that they pass in front of your face and the toes touch the ground.

Now, it may not be possible for you to touch the ground at first, and I don't want you to strain too much if you cannot.

Just show patience and perseverance and everything will become easy… with time.

The 10th Exercise

For this you'll need a pull up bar that is at least a foot higher than your natural height.

Jump up and grab the bar, and then simply swing on it gently forwards and backwards until your hands are tired.

Some training advice for the Advanced Set of exercises:

So these were the advanced set of exercises. Remember that it's essential that you perform all ten of these exercises every day, morning and evening for a period lasting at least four weeks, though I recommend that you continue using these exercises for a period that is considerably more than four weeks or so.

You should find a continuous increase in height over this period of four weeks, but according to me, you should continue this program so long as your height continues to increase and only stop it at a point when the increase in height seems to have plateaued out at a certain maximum. None of these exercises are hard or impossible to do, and all you need is a certain level of dedication, but more than that – all you need is a certain small amount of time given to them every morning and again just before you go to bed.

This isn't much of a sacrifice to make for the gains that are possible. The simple fact is that only putting in the necessary effort will result in

any level of progress, and without that effort you'll remain at the static height that you were when you reached adulthood.

While these exercises do work better for a younger person, it has been found that the gains seen through this exercise program are visible across all age groups. Just be careful to follow the regimen exactly, and to pay careful attention to the diet program, and you'll see results.

Chapter Eight: Some Additional Training Advice

There are some other ways in which you can boost and maintain your gained height.

Sitting correctly:

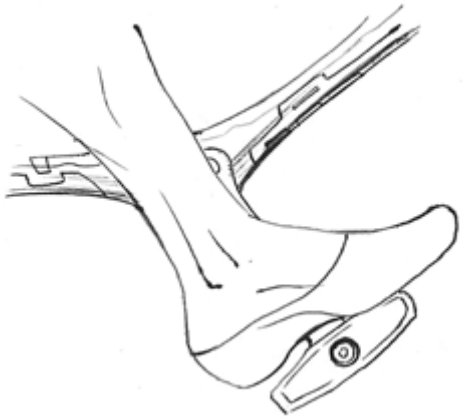
One important method of retaining your height gains is sitting correctly. Look at the picture below.

Sitting in this manner, with the spine complete straight and at a diagonal to the floor, is perhaps the best way to take pressure off the spine when sitting. You can use pillows to maintain this position.

Riding a bicycle:

Did you know that simply riding a bicycle can help you gain height – especially if you do it regularly.

Simply raise your bicycle seat so that you have to extend your legs completely (and even stretch them slightly) to pedal. Raise the handles as well, so that you can ride your bike with your back erect.



Pedal so that you feel a slight stretching of the legs as you ride, and you will see an increase in height from this exercise alone in time.

Just remember that you should ride with your feet flat on the pedal, as shown in the picture to the left, rather than using your toes to make up for the fact that you can't reach the pedals properly. If your pedals are slightly out of reach and your feet are on the pedals, your legs will adapt to this by stretching slightly, leading to an increase in height.

As a matter of fact, any activity that allows the spine to relax or allows the body to stretch can be a benefit to one's height.

Swimming is good, as I've said, but other activities like basket ball and volleyball and even tennis can be beneficial. Experiment a bit and see what you enjoy and what works for you.

Keep pushing your limits, stretching the muscles, bones and ligaments of your body. Until you reach your maximum possible height, remember, there's always room for growth, so long as you keep working at it, so long as you stay dedicated and disciplined, and most of all, so long as you never, ever lose sight of your goals.

Success is within your reach – you just have to stretch upwards to reach it. So what are you waiting for?

Lots More Information & Tips!

Chapter Nine

Chapter Nine: Lots more Information and Tips!

The Growth Process

Everyone grows and nobody can prevent the growth process, it's just a natural part of our lives. Of course, while we all grow, some of us grow quicker than others. This is because not everyone hits their growth spurt at the same time. It can happen in short bursts or it can happen all at once.

If there is a delay in growing when it comes to children, however, they should be seen by a doctor to make sure there aren't any problems. Some children experience growth defects and you want to make sure this is something you can still completely rule out by visiting your doctor.

Did you know that there are 300 bones in your body when you are first born? Did you also know that there are only 206 bones by the time we reach adulthood? Why does this happen? Mainly because our bones are basically cartilage when we're babies which is why

baby's bones are so much more susceptible to break with light impact.

As we get older our bones go through what is called 'ossification' where the cartilage turns solid. Eventually all of the smaller bones will unite and then be one large bone therefore reducing the total number of bones in our body.

Growth plates are located at the ends of some of the long bones in our body. When some of the cartilage doesn't ossify all at the same time, these plates continue to make new tissue while the old tissue turns into bone. Therefore making you grow even more.

Once you stop growing which is usually when you are an adult, the plates will ossify as well, leaving you at your final height. If something damaging happens to these growth plates while you are still young, your growth could be stunted and could cause some bones to be more mature than others, and some longer than others.

You can actually estimate the potential height of a child by watching their growth pattern.

A female will usually have a full height of double her height when she is three years old. A male will usually have a full height of double his height when he is three years and three months old.

Maximizing Growth

While in the growing stages there are lots of various things you can do to help yourself grow even taller. The way you carry yourself and how you live your life equally affect you in many ways. Both will have an effect on your appearance, how you feel and also your growth height.

It’s the same as striving to be the best you can be, no matter what obstacles may come across your path. You must be willing and able to give one hundred percent in order to achieve your maximum growth. Keep reading to learn about some factors that need your consideration.

Now, one thing that can really enhance growth is levels of human growth hormone. If you remember, we discussed this in some detail at the beginning of this book, and I even taught you to make a HGH drink. Well, it’s also possible to enhance your levels of HGH through exercise, and this gives even better results because you will gain muscle mass which in turn will make you look even better. This is usually the main goal of people interested in height enhancement.

Of course you will have to make sure that the exercise you are doing is going to help you reach your goals. Naturally increasing your HGH release can be done with strength training as it is a rather intense type of exercise and helps provoke tissue growth.

People have noticed hormone release results when lifting heavy weights at least 8-12 times while resting for a minute in between. You don’t want to rest too long in between or the release will decrease so use just enough time to recover from the first rep.

Exercises that use the most muscle fibers should be added to your regimen. Exercises made solely for isolation should be avoided. For example, do squats and bench presses over pectoral flyes and leg extensions.

Exercise also contains a cardiovascular stage and during this time is when the growth hormone release is very distinguished. Even more so when it’s an intense workout that lasts no more than fifteen minutes.

You do have the option of doing high intensity workouts for at least 10 minutes in order to get your heart rate up. Or you can opt for doing exercises in short amounts, lasting up to 30 seconds each. Either one of these will benefit your by provoking HGH release along with burning fat and increasing your metabolism.

On the other hand doing exercise sessions that last a substantial amount of time aren't proven to be helpful and even decrease instead of increase your release of HGH. Strength training will also put out cortisol which is degrading to the tissue and is against the actual goal you are trying to reach.

It's all actually very simple. Work out really hard then call it day and rest if you want to increase your HGH levels. If you work out continuously and find you are in the gym more often than not, then you aren't going to achieve the same results.

Preventing your growth from being stunted

While you can always try different ways to help gain height, many people do not realize it's equally important to make sure you aren't doing something that can hinder your height growth. By being aware of this beforehand, you can prevent spending large amounts of money on treatments that will not work because something in your daily life style is doing the exact opposite, therefore canceling the treatment out and sending your money down the drain. The following are some things you should consider and be aware of before taking any height growth treatments.

Malnutrition:

Malnutrition is probably the largest factor that can hinder your growth. If you aren't consuming the proper foods then your body cannot grow like it is supposed to. Your body needs continuous nutrition in order for your metabolism to work properly. The metabolism will slow down when the body is lacking the proper nutrients leaving you distanced from your full growth potential.

You can actually calculate your calorie intake to find out how many calories your own personal body needs on a daily basis. This is a great way to make sure your diet contains the proper food that will help support your growth. If you find that you getting the amount you should, then you can consider the different ways to get more calories in order to give your body the right nutrients and energy.

An easy and fast method to calculate your calories is using the Harris-Benedict formula below.

Males: 66 + (6.3 multiplied by your weight) + (12.9 times your height, in inches) – (6.8 times your age)

Females: 655 + (4.3 multiplied by your weight) + (4.7 times your height, in inches) – (4.7 times your age)

This method will tell you how many calories you should be consuming in order for your body to properly function. If you are actually consuming less than you should, certain parts of your body could be in jeopardy. If so, your bone growth could be what is being hurt the most.

Unless you just lay in bed all day long, you will also have to consider the amount of calories you're expending every day. You can use an estimate since this number will vary depending on each individual.

Use the estimate you have for your BMR and then times it by:

° 1.2 if you are not regularly physically active

° 1.375 if you are physically active 1-3 times a week

° 1.55 if you are physically active 3-5 times a week

° 1.725 if you are physically active 6-7 times a week

° 1.9 if you are very active or have a physical job

Now you have a better understanding of what you should try to consume every day when it comes to calorie consumption.

In order to have a balanced diet it will need to consist of 15-20 percent protein, 15-35 percent fat, and 50-65 percent carbohydrates. You should also be aware that each fat gram you consume has 9 calories while protein and carbs have 4 calories. You can ensure your diet has all the minerals and vitamins your body needs by implementing lots of fruits and vegetables into your diet.

Fasting has been shown to raise growth hormone levels but it's not exactly the smartest way to do this. Your body needs food so if you want to get the best results just lower your calorie intake. You want to get the amount your body needs, as you found out above, but no more than what you need. People today struggle with obesity and decreased HGH levels because of the over consumption of calories

Hypothyroidism:

This is a condition that some people endure and that could end up hindering their growth. This condition is actually a disease; one that consists of your body lacking the proper amount of the thyroid hormone. The thyroid is what maintains your metabolism so if the thyroid isn't functioning like it should your metabolism will go down and you could start seeing the effects.

There are various symptoms associated with hypothyroidism and they include: increase in weight, weariness or fatigue, feeling cold often, loss of hair, dry skin or hair, muscle pains, aches, or cramps, loss of memory, suppressed libido, irritability, and depression.

Your bones grow when certain processes take place that form new bone tissue. If these processes are slowing down, that means your height will be slowed down as well.

If you think you might be suffering from hypothyroidism it is recommended that you talk with your doctor. They can perform specific tests to see if you might be missing some of this hormone

then give you an effective treatment to help. With the right treatment you can take care of this disease while noticing a bit of normal growth.

Hypogonadism:

This is a disease that can alter the reproductive system so that the testes or ovaries aren't functioning properly and are producing less sex hormone than normal. This can hinder the sexual development process and possibly cause infertility.

Testosterone is a rather big hormone and has an important role in the growth of the body. Because of this, it's important that the amount is decreased in order to reach your potential height. If this decrease happens before puberty you may not even go through sexual development. If this decrease happens after puberty it could cause sexual dysfunction.

There are ways to treat Hypogonadism, one of these treatments consisting of replacing the sex hormone. This can usually heal the symptoms that occur when low testosterone levels are experienced.

If you believe you might have Hypogonadism you should consult your doctor right away. The more preventive and even early treatment you get the better chance you have of overcoming the disease.

Osteoporosis:

For people who are diagnosed with osteoporosis at a rather early age suffer the truth that their bones will become weakened and even depleted which can cause hindered growth. This is why it is always highly recommended that people take preventive care as to avoid the risk of developing osteoporosis at any age but specifically young ages.

There are different preventive factors you can consider to avoid osteoporosis. Some of these preventive treatments include getting a high amount of Vitamin D, especially in the winter time, exercising regularly with weights, getting the right amount of calcium, avoiding tobacco use and keeping a close eye on your alcohol consumption. Clearly some of these are targeted more towards adults but it’s never too early to teach young children about the importance of bone health and osteoporosis prevention.

Height Enhancement for The Intelligent Adult…

Chapter Ten

Chapter Ten: Height enhancement for the intelligent adult…

Once you are an adult you are more limited as to just what you can do to help gain height because you already endured the growth processes earlier in your life. Luckily, there are still many ways you can get taller.

Exercises:

Doing the exercises mentioned in the previous chapters is the most effective and scientifically proven way to increase your height - especially if you are an adult.

Improving Posture:

Your posture is one way to improve your height. By slouching we appear shorter than we are and slouching can also make us look less assured of ourselves. Take this moment to consider a time when someone made quite an impression on you.

Was their head up, shoulders back, and did they seem to radiate confidence? Their posture has a lot to do with the impression you

received. It really can make a big difference on how others perceive you as well.

Having constant good posture will not only make you look taller but your height will gradually increase. Habitual slouching or bad posture can actually make you shorter as well. No matter what you are doing, if your body is slouched your spine muscles will shorten in time.

They also won’t be as flexible as they were before and you could lose some height. This is something you want to avoid at all costs because it will take much effort on your part, to fix.

You can work on your posture by gaining strength to your back muscles. There are various ways of going about this. One of those ways is by implementing a weight lifting regimen, making sure you have exercises such as stiff-legged dead lifts, single arm rows and shrugs, and bent over rows as well. These types of exercises work the back muscles and are vital to keeping your shoulders in their proper position and strengthening and straightening the back.

A different way to build your back muscles if you have a desk job is by squeezing your shoulder blades together while also pulling your shoulders back. Do this ten times every 3 hours or so. While this helps build your back muscle you will also become more aware of your posture. If you feel that your body is in a different position while doing the exercises, then you probably don't have good posture and this exercise will help tremendously.

Last but not least, once your body understands proper posture, it's up to you to keep it that way. This is actually pretty easy compared to the first changes you had to make because your body will feel better with the right posture. You should still keep in mind not to move your body in ways that can effect your alignment.

Next time you walk in front of a mirror, glance in it to see how you stand. Are your shoulders back or slumped? Is your head lifted or lowered? If your shoulders are back and your head is lifted you should already look taller than before you implemented the exercises and modifications. If they aren't, you need to work more on muscle

development and be more conscious of your body until you are used to standing in a healthier natural way.

Looking Taller:

Now we will talk about some small things you can do concerning grooming and caring for yourself in order to appear taller. The first thing up for consideration is the way you dress. Generally you want to choose solid colors to appear as tall as you can. If you choose a top in a different color than your bottoms, you will look a lot shorter.

Something else to remember is wearing vertical stripes can make you look slimmer and taller. The same doesn't go for checked patterns or plaid shirts.

Darker colors and light clothing materials also help you appear taller.

Also, you should not forget that wearing ill-fitting clothes can make your body seem disproportioned and just draw more attention to both your height and the way you look.

When it comes to purchasing a jacket or blazer, opt for those with plenty of buttons down the front. Ones with say, 3 buttons, will make you appear shorter. Choosing one that is long in length, that ends right below the seat of your pants, can help you appear taller and add length to your frame. Do not wear turtlenecks as they make the neck look shorter. Instead, go for v-neck tops because they can add a great amount of length.

Your pants will also make a difference in how tall you appear. Choose those that sit right above your hips to give you longer legs. While the low-rise ones are the current trend, they sometimes make your legs look shorter so you aren't achieving your primary goal. Also try not to wear any cuffed or pleated pants.

Your shoes will also have an effect on your height and can be a great way to increase your height. Shoes that have a heel of any size will help you seem taller. Keep in mind that the taller the heel of your shoe, the longer your pants will need to be as well. Choosing pants that are too short for the shoes you are wearing can make you seem even shorter than you really are.

Chunky natured styles are a great choice because they hide your feet so they don't appear to be too small. If needed, add some insoles to your shoes to get an extra height boost.

Now let's discuss your hairstyle. Men should actually avoid longer hair because they fuse with your shoulders making your neck look short and giving you a not so neat appearance. Short, well kept hair styles can add sophistication to your overall look.

Lastly, pay attention to your physical appearance. Heavy people tend to appear shorter and stockier than they really are. Keeping a lean physique can add length to your appearance and even add attractiveness.

By remembering all these factors and implementing them will help you take the most advantage of your natural height. Test different outfits to figure out what your body looks best in and what suits your own personal taste. One of the utmost important things you can remember during this process is that you should be comfortable in your entire outfit and appearance. Otherwise you may not be able to

pull off looking taller because you lack the confidence thanks to the uncomfortable clothing.

Resisting the onset of age:

Once you feel more comfortable with how tall you are, there are ways you can maintain your height and prevent losing height that can come along with aging.

The first and most effective way to maintain your height is by following the preventive care of osteoporosis. This disease is a common and serious one that hurts your bone growth and health. Make sure you are consuming lots of calcium on a daily basis along with regular exercises or activities that involve weight.

Your own weight can also maintain your height. Those who are overweight will be putting pressure on their spine because their spine is what bears this extra weight. After awhile, this can cause the vertebral column to compress. In addition, you could start experiencing back pain that of course will limit your physical movement ability. All around it is something better avoided so make sure you’re maintaining a healthy weight and you can maintain your height as well.

Another disease that can occur is disc degeneration. This happens in your joints whenever the inside of the disc becomes unorganized and slowly starts falling apart inside the disc. This entire process of disc degeneration can have a huge impact on the ability for the discs to bear that much of a weight load. If the process is highly extreme you will start to notice a decrease in your height.

This is because the discs start compressing and cannot move as well. You should keep an eye on your back and consult your doctor immediately if you notice any changes to your back. This could be any area protruding, etc. If you see anything like this you want to try and catch it before it gets too extreme.

Lastly, some people think that they can prevent a decrease in their height by using anti-gravity remedies. This consists of hanging upside down for a certain amount of time in order to decrease the stress placed on your vertebrae and elongating your back. However you are not going to actually grow from this remedy but you can decrease any back pain you might have. It can release any pressure you might have in your back and will just make you feel much better.

Now you have a variety of general procedures that can help you maintain your height and also hinder any additional decrease in height while making you appear taller in a natural way. By using these ideas you will notice a vast improvement on just how tall you actually look to be.

Height Increase Scams & How to Counter Them…

Chapter Eleven

Chapter Eleven: Height Increase Scams and how to counter them…

When you are searching for something health related you always need to be aware of the variety of scams that are out there. A majority of these scams will claim you will see major improvements in a very short time. The best choice you can make is doing some research on anything health related that you are curious about because if the proper caution isn't taken you could risk hurting your health.

Listed below are a few scams that you need to be aware of. They might sound like they're legitimate but most of the time you won't see any changes in your height.

Reflexology:

This is a technique practiced for treating symptoms by the use of focusing on individual pressure spots located on the feet. The specialist will begin by applying pressure to these spots on your feet. After a certain amount of time they start to see specific changes

in your feet. They focus on these changes and after some time you are supposed to notice an improvement. They apply pressure differently depending on your problem areas.

Typically the technique only takes an hour and more sessions might be suggested depending on your specific needs. You will want to make sure you find a certified specialist and you can do so by verifying they are certified from the Association of Reflexology. Just keep in mind that there is no hard proven medical proof that this increases your height. Worst case scenario; you will get a very nice relaxing foot massage.

Reflexology insoles are available in some stores and they claim to give the same results of actual reflexology. Again, keep in mind that by applying even the smallest amount of pressure to your feet is not likely to provoke your hormones in a way that will trigger your height growth.

Hypnotism:

Another common height increase scam that has become quite popular is hypnotism. Hypnosis is when a person brings you to an intense relaxed state that is elusive. Now when they say something to you while you are in this state, you begin to believe what they are saying. The theory behind this technique is based upon ‘I think therefore I am’. This theory is thought to control habitual thoughts because it’s aiming at the subconscious state of mind therefore it feels it can manipulate your everyday life.

Of course your mind is responsible for a large potion of the way you think and act, it alone with your thoughts is not able to provoke growth. This process is more physiological and is why specific body processes need to be in duration. Hypnosis can be beneficial for many other things like helping to overcome addictions, it doesn’t benefit actual body changes or provoke height growth.

Herbal Supplements:

If you glanced at the available herbal supplements on the market today that claim to enhance height you should be forewarned that they are most likely a scam. A majority of these products state that they provide help for the pituitary gland which will help promote height growth.

In reality these herbal supplements are more for improving your overall well-being, health, and immune system which in turn will help promote growth but only if you are still young enough and in the growth stages. The herbal supplements alone, without the growth process, will not benefit your height in any way.

Magnetic Insoles:

Some people believe magnetic insoles can help enhance height growth. The insoles state they are similar to reflexology in the way that they operate; provoking specific organs and nerves in your body. Magnetic insoles have also said they help your blood circulation and give you increased energy.

While it has been proven that certain magnetic therapy can somewhat offer assistance for pain relief, as of present there isn’t any scientific proof that the insoles give any height assistance.

Conclusion

Chapter Twelve

Chapter Twelve: Conclusion

There are various points that participate in your growth process. Some are more controllable by you while others aren't controllable by you at all. By implementing proper factors and points that you control you can help prevent any future decreases in height.

While in the growing years the best and probably most important thing you can do is get the right nutrition. It doesn't matter how many points you need to consider at the time.

If you aren't getting the nutrition your body needs in order for your bones to grow, then there isn't much chance that you will reach your potential height.

In addition to overall proper nutrition and calorie consumption, you must give your body enough calcium to ensure prevention of broken bones. You can also decrease any risk of osteoporosis in the future.

You can help your body give more HGH release by taking supplements. The right amount of sleep is also beneficial to this so if you need help with getting proper sleep you could consider using a supplement like melatonin.

Once you are beyond your growing years there is still hope in adding height by doing a proper grow taller exercise program.

Having good posture will be of utmost importance then it will be ways of dressing appropriately and wearing proper shoes.

Height increasing scams also need to be watched out for. You want to prevent spending wasted money and you don’t want to risk your health using unsupported methods.

Taking good care of your body is beneficial in many ways. You will believe you can reach your potential height and you will also notice a difference in your overall health.

You will lack the confidence needed in order to feel good about yourself to help reach your maximum health. Confidence also brings attractiveness so working internally to improve this is very beneficial.

If you are young and currently still growing do not worry because everyone grows at their own individual time. Some people grow taller in the earlier years while others aren't growing taller until they're a teenager or a young adult.

If you are concerned about your current height don't hesitate to call your doctor. You want to avoid the chance you have a serious disease or abnormality. They can be treated if they aren't in a prolonged stage and getting the growth process back to normal is typically the easy outcome.

If you ignore any concern you have chances are you will only be disappointed. Never be afraid to ask your doctor about anything that is on your mind or is worrying you.

You can ease your mind and help prevent any possible problems.

Our bodies are continuously growing. When in old age, our bones still have to develop brand new cells in order to substitute the old ones.

Just follow the guidelines mentioned in earlier sections of this book as they can help you reach that point in your life when you are completely satisfied with your overall height.
